Stickiness  
phenomenon

Stickiness for  
antisymmetric data

Three further  
questions

## Nonlocal minimal surfaces

Energy functional dealing with “*pointwise interactions*”  
between a given set and its complement

Main idea: the “surface tension” is the byproduct of long-range  
interactions

Implications: nonlocal phase transitions and nonlocal  
capillarity theories

New effects due to the long-range interactions

Contributions from “far-away” can have a significant influence  
on the local structures of these new objects

**STICKINESS** Differently from classical minimal surfaces, the  
nonlocal minimal surfaces have the strong tendency to “stick  
at the boundary”

# The fractional perimeter functional

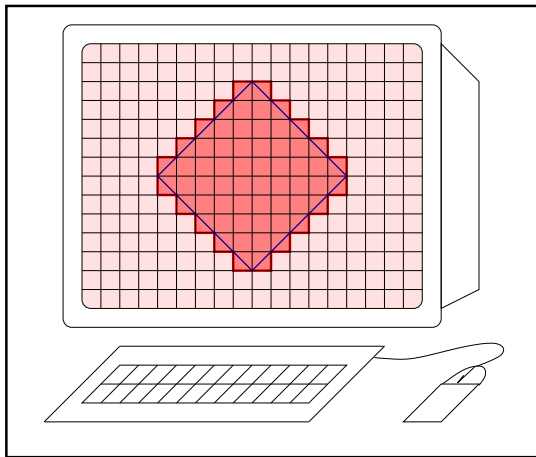

Given  $s \in (0, 1)$  and a bounded open set  $\Omega \subset \mathbb{R}^n$  with  $C^{1,\gamma}$ -boundary, the  $s$ -perimeter of a (measurable) set  $E \subseteq \mathbb{R}^n$  in  $\Omega$  is defined as

$$\begin{aligned} \text{Per}_s(E; \Omega) &:= L(E \cap \Omega, (\mathcal{C}E) \cap \Omega) \\ &\quad + L(E \cap \Omega, (\mathcal{C}E) \cap (\mathcal{C}\Omega)) + L(E \cap (\mathcal{C}\Omega), (\mathcal{C}E) \cap \Omega), \end{aligned}$$

where  $\mathcal{C}E = \mathbb{R}^n \setminus E$  denotes the complement of  $E$ , and  $L(A, B)$  denotes the following **nonlocal interaction term**

$$L(A, B) := \int_A \int_B \frac{1}{|x - y|^{n+s}} dx dy \quad \forall A, B \subseteq \mathbb{R}^n,$$

This notion of  $s$ -perimeter and the corresponding minimization problem were introduced in [Caffarelli-Roquejoffre-Savin, 2010].

Side 1.

Perimeter 4.

Approximate Perimeter  $4\sqrt{2}$ .

Error  $4(\sqrt{2} - 1)$ .

Error in each pixel  $O(\epsilon^{2-s})$ .

Number of pixels  $O(\epsilon^{-1})$

Error  $O(\epsilon^{1-s})$ .

## 1) Existence theorem:

there exists  $E$   $s$ -minimizer for  $\text{Per}_s$  in  $\Omega$  with  $E \setminus \Omega = E_0 \setminus \Omega$ .

## 2) Maximum principle:

$E$   $s$ -minimizer and  $(\partial E) \setminus \Omega \subset \{|x_n| \leq a\} \Rightarrow \partial E \subset \{|x_n| \leq a\}$ .

3) If  $\partial E$  is an hyperplane, then  $E$  is  $s$ -minimizer.

4) If  $E$  is  $s$ -minimizer in  $B_1$ , then  $\partial E$  is  $C^{1,\alpha}$  in  $B_{1/2}$  except in a closed set  $\Sigma$ , with Hausdorff dimension less or equal than  $n - 2$ .

5) If  $E$  is  $s$ -minimizer and  $0 \in \partial E$ , then

$$\int_{\mathbb{R}^n} \frac{\chi_E(y) - \chi_{E^c}(y)}{|y|^{n+s}} dy = 0.$$

## 1) Existence theorem:

$s$  close to 1: nonlocal minimal surfaces are as regular as classical minimal surfaces.

(If  $E$  is  $s$ -minimizer in  $B_1$ , then  $\partial E$  is  $C^{1,\alpha}$  in  $B_{1/2}$  except in a closed set  $\Sigma$ , with Hausdorff dimension less or equal than  $n - 8$ .)

[Maz'ya-Shaposhnikova, 2002] and  
[Dipierro-Figalli-Palatucci-Valdinoci, 2013]:  
If there exists the limit

$$\alpha(E) := \lim_{s \searrow 0} s \int_{E \cap (CB_1)} \frac{1}{|y|^{n+s}} dy,$$

then

$$\lim_{s \searrow 0} s \operatorname{Per}_s(E, \Omega) = (\omega_{n-1} - \alpha(E)) \frac{|E \cap \Omega|}{\omega_{n-1}} + \alpha(E) \frac{|\Omega \setminus E|}{\omega_{n-1}}.$$

# Stickiness to half-balls

For any  $\delta > 0$ ,

$$K_\delta := (B_{1+\delta} \setminus B_1) \cap \{x_n < 0\}.$$

We define  $E_\delta$  to be the set minimizing the  $s$ -perimeter among all the sets  $E$  such that  $E \setminus B_1 = K_\delta$ .

Introduction

Limits

Stickiness  
phenomenon

Stickiness for  
antisymmetric data

Three further  
questions

There exists  $\delta_o > 0$  such that for any  $\delta \in (0, \delta_o]$  we have that

$$E_\delta = K_\delta.$$

Given a large  $M > 1$  we consider the  $s$ -minimal set  $E_M$  in  $(-1, 1) \times \mathbb{R}$  with datum outside  $(-1, 1) \times \mathbb{R}$  given by the jump  $J_M := J_M^- \cup J_M^+$ , where

$$J_M^- := (-\infty, -1] \times (-\infty, -M)$$

and 
$$J_M^+ := [1, +\infty) \times (-\infty, M).$$

There exist  $M_o > 0$  and  $C_o \geq C'_o > 0$ , depending on  $s$ , such that if  $M \geq M_o$  then

$$\begin{aligned} & [-1, 1) \times [C_o M^{\frac{1+s}{2+s}}, M] \subseteq E_M^c \\ \text{and} \quad & (-1, 1] \times [-M, -C_o M^{\frac{1+s}{2+s}}] \subseteq E_M. \end{aligned}$$

Also, the exponent  $\beta := \frac{1+s}{2+s}$  above is optimal.

# Stickiness to the sides of a box

Nonlocal minimal  
surfaces

questions

# Instability of the flat fractional minimal surfaces

Fix  $\epsilon_0 > 0$  arbitrarily small. Then, there exists  $\delta_0 > 0$ , possibly depending on  $\epsilon_0$ , such that for any  $\delta \in (0, \delta_0]$  the following statement holds true.

Assume that  $F \supset H \cup F_- \cup F_+$ , where

$$H := \mathbb{R} \times (-\infty, 0),$$

$$F_- := (-3, -2) \times [0, \delta)$$

and

$$F_+ := (2, 3) \times [0, \delta).$$

Let  $E$  be the  $s$ -minimal set in  $(-1, 1) \times \mathbb{R}$  among all the sets that coincide with  $F$  outside  $(-1, 1) \times \mathbb{R}$ .

Then

$$E \supseteq (-1, 1) \times (-\infty, \delta^{\frac{2+\epsilon_0}{1-s}}].$$

With the Euler-Lagrange equation up to the boundary, we can take any configuration, add an arbitrarily small bump and use the unperturbed configuration as a barrier.

At touching points the additional bump produces an extra-mass violating the Euler-Lagrange equation.

Notice that now also touching at the boundary can be taken into account!

Think about the usual suspects (discontinuous, Lipschitz, Hölder, smooth).

Blow-up.

The “worst” cases to understand are the Hölder and the smooth (the Lipschitz produces non-minimal corners).

The smooth case produces flat objects: use a boundary improvement of flatness (combined with a boundary monotonicity formula) to deduce smoothness of the initial minimizer (for this, use new barrier to go beyond the linear theory!).

The Hölder case produces vertical angles: rule them out by proving that close-to-vertical nonlocal minimal graphs are indeed vertical (for this, slide balls).

Three further questions

## How “nonlinear” is the problem?

The linearization of the trace of a nonlocal minimal graph is given by the fractional normal derivative of a fractional Laplace problem.

Indeed, if  $u$  is a nonlocal minimal graph, say in  $x \in (0, 1)$ , and it is  $\varepsilon$ -flat near the origin, then  $\frac{u}{\varepsilon}$  (the “vertical rescaling”) tends to a function  $\bar{u}$  which is a solution of  $(-\Delta)^{\frac{1+s}{2}} \bar{u}(x) = 0$  for  $x \in (0, 1)$ .

By the boundary regularity of linear equation (Serra, Ros-Oton, Grubb, etc.) the first order of  $\bar{u}$  is of Hölder type: near the origin  $\bar{u} \simeq ax^{\frac{1+s}{2}}$ , for some  $a \in \mathbb{R}$ .

So, one may expect that, near the origin,  $u(x) \simeq a\varepsilon x^{\frac{1+s}{2}}$ .

But since  $|u(x, 0)| \leq Cx^{\frac{1+s}{2}}$ , one is tempted to guess that necessarily  $a = 0$ .

How “nonlinear” is the problem?

The linearization of the trace of a nonlocal minimal graph is given by the fractional normal derivative of a fractional Laplace problem.

Indeed, if  $u$  is a nonlocal minimal graph, say in  $x \in (0, 1)$ , and it is  $\varepsilon$ -flat near the origin, then  $\frac{u}{\varepsilon}$  (the “vertical rescaling”) tends to a function  $\bar{u}$  which is a solution of  $(-\Delta)^{\frac{1+s}{2}} \bar{u}(x) = 0$  for  $x \in (0, 1)$ .

By the boundary regularity of linear equation (Serra, Ros-Oton, Grubb, etc.) the first order of  $\bar{u}$  is of Hölder type: near the origin  $\bar{u} \simeq ax^{\frac{1+s}{2}}$ , for some  $a \in \mathbb{R}$ .

So, one may expect that, near the origin,  $u(x) \simeq a\varepsilon x^{\frac{1+s}{2}}$ .

But since  $|u(x, 0)| \leq Cx^{\frac{3+s}{2}}$ , one is tempted to guess that necessarily  $a = 0$ .

# Flexibility of linear equations

[Dipierro-Savin-Valdinoci, 2020]

But this is **not** the case! The fractional normal derivative of a fractional Laplace problem is not only different than zero in general, but it can be **arbitrarily prescribed**:

Let  $n \geq 2$  and  $f \in C(\mathbb{R}^{n-1})$ . Then, for every  $\delta > 0$  there exist  $f_\delta, u_\delta \in C(\mathbb{R}^{n-1})$  such that

$$\begin{cases} \sup_{|x'| \leq 1} |f_\delta(x') - f(x')| \leq \delta, \\ (-\Delta)^\sigma u_\delta = 0 \text{ in } \mathcal{B}_1 \cap \{x_n > 0\}, \\ u_\delta = 0 \text{ in } \{x_n < 0\}, \\ \lim_{x_n \searrow 0} \frac{u_\delta(x)}{x_n^\sigma} = f_\delta(x') \text{ for all } |x'| < 1. \end{cases}$$
